## **Digital Image Processing Course Report**

[Mask R-CNN: Comprehensive Study of Instance Segmentation]

#### **Course Information**

Course Name: Digital Image Processing

Academic Year: 2024 Fall Semester

#### **Student Information**

• Name: 蒋云翔

Student ID: 2022102330

Major: Computer Science and Technology

Class: 22CST

#### Instructor

Dr. Qingfeng Zhang (张庆丰)

#### **Submission Information**

• Submission Date: [December 21, 2024]

Report Type: [Algorithm Research]

International School, Jinan University

### **Abstract**

Instance segmentation is a critical task in computer vision that requires both object detection and pixel-level segmentation, providing detailed delineation of object boundaries. The Mask R-CNN model, introduced by He et al. in 2017, represents a significant advancement in this field by extending the Faster R-CNN architecture to incorporate a segmentation mask branch. This model not only detects objects and classifies them but also predicts precise binary masks for each detected instance, enabling accurate segmentation even for overlapping objects. In this report, we provide a comprehensive study of Mask R-CNN, detailing its architecture, training process, and evaluation using the Balloon dataset. We analyze the performance of the model in terms of key metrics such as Mean Average Precision (mAP), Intersection over Union (IoU), and training loss curves. Additionally, we discuss the strengths and limitations of the model, including challenges in handling occlusions and computational efficiency. The report also explores potential future improvements, such as multi-scale training, attention mechanisms, and lightweight architectures for real-time applications. Our findings demonstrate that Mask R-CNN achieves high accuracy in instance segmentation tasks and offers a flexible framework that can be adapted to various practical applications in fields like autonomous driving and medical imaging.

### 1. Introduction

Instance segmentation is one of the most challenging tasks in computer vision. Unlike traditional object detection, which only identifies and classifies objects within bounding boxes, instance segmentation involves detecting and segmenting each object at the pixel level. This task not only identifies object locations but also captures fine-grained details of their shapes and boundaries, which is especially useful for applications such as medical image analysis, autonomous vehicles, and image editing.

A breakthrough in the field of instance segmentation is the **Mask R-CNN** model, proposed by He et al. in 2017. It combines the power of **Faster R-CNN** for object detection with a novel mask prediction branch to perform instance segmentation. This unified framework allows for pixel-wise segmentation of each object, providing high accuracy in both bounding box prediction and segmentation mask generation.

### 1.1 Background

Traditional object detection methods, such as **R-CNN** and **Fast R-CNN**, leverage region proposals and convolutional neural networks (CNNs) to classify and localize objects. However, these methods failed to address the need for precise pixel-wise segmentation, which is a critical aspect of many advanced computer vision applications.

Mask R-CNN overcomes this limitation by introducing a new branch that predicts segmentation masks for each detected object. This extension of Faster R-CNN enables fine-grained segmentation and provides significant improvements over earlier methods,

particularly in tasks requiring detailed object delineation.

#### 1.2 Problem Statement

Instance segmentation combines the challenges of both object detection and semantic segmentation:

- **Object Detection**: The model needs to correctly identify the location of objects using bounding boxes.
- **Semantic Segmentation**: The model labels each pixel in the image according to its class but does not distinguish between instances of the same class.
- Instance Segmentation: The model must go beyond these two tasks by differentiating between different instances of the same object class and generating a precise mask for each individual object.

Mask R-CNN achieves this by using a separate segmentation mask for each object instance, enabling it to perform instance-level segmentation. This is crucial in real-world applications, where objects often overlap or have complex shapes.

### 1.3 Objectives

This report aims to:

- Provide a detailed explanation of the **Mask R-CNN** architecture.
- Examine the training process, including dataset selection, model configuration, and hyperparameters.
- Evaluate the performance of Mask R-CNN on the Balloon dataset and discuss the results.
- Analyze the strengths and limitations of Mask R-CNN and explore potential future improvements.

## 2. Methodology

#### 2.1 Mask R-CNN Architecture Overview

Mask R-CNN is built on the **Faster R-CNN** architecture, which consists of several key components:

- Backbone Network: This is the core feature extractor, usually a pre-trained CNN such as ResNet or ResNeXt. The backbone processes the input image and generates feature maps, which are then used for region proposal generation and mask prediction.
- 2. Region Proposal Network (RPN): The RPN generates region proposals based on the feature maps. These are regions that are likely to contain objects. The RPN works by sliding a small window over the feature maps and producing anchor boxes for each location. The RPN then classifies these anchors as either foreground or background and refines the bounding box locations.

- 3. RolAlign: RolAlign improves upon the RolPool operation used in Faster R-CNN by avoiding spatial quantization. RolPool approximates the spatial locations of the regions, which can lead to misalignment and loss of fine-grained information. RolAlign, on the other hand, uses bilinear interpolation to preserve spatial accuracy, which is essential for accurate mask predictions.
- 4. Segmentation Masks: Mask R-CNN adds an additional branch to the Faster R-CNN architecture. This branch is a fully convolutional network (FCN) that generates binary segmentation masks for each detected object. These masks are output at a low resolution (28x28), which is then upsampled to the size of the input image.

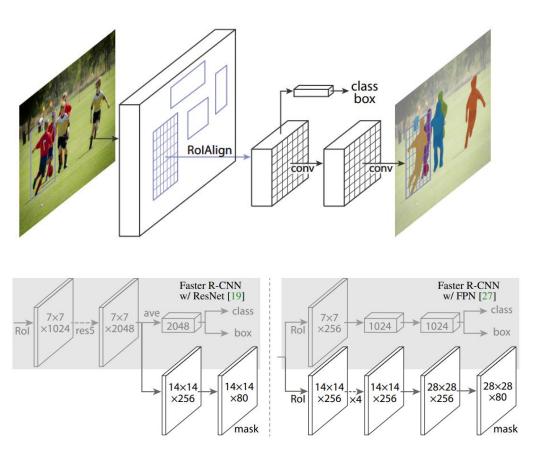

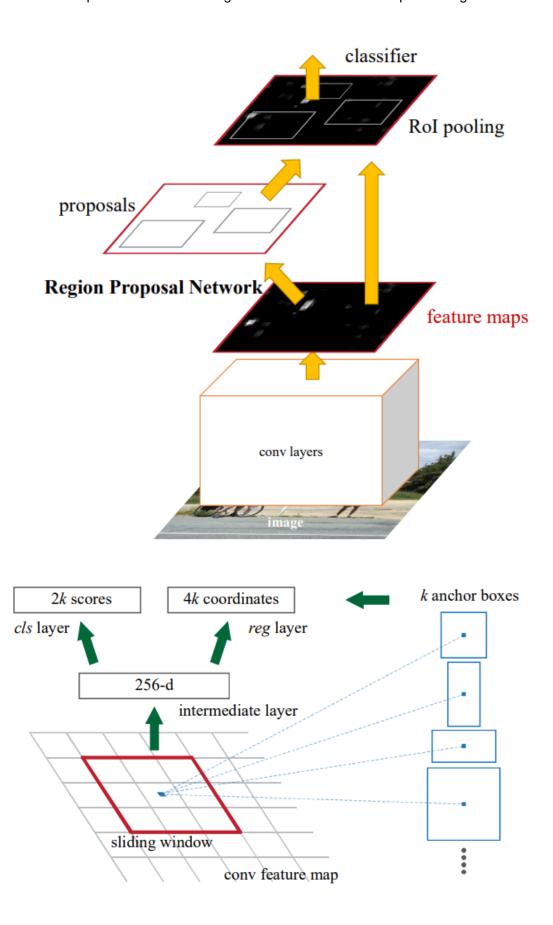

Figure 1: The architecture of Mask R-CNN, showing the backbone, RPN, RolAlign, and mask branch.

### 2.2 Region Proposal Network (RPN)

The **Region Proposal Network (RPN)** is a crucial component of Mask R-CNN. It generates potential object regions, or **regions of interest (Rols)**, based on the feature map extracted by the backbone network. The RPN works by sliding over the feature map and producing a set of **anchor boxes** at each position. Anchor boxes are predefined bounding boxes with different aspect ratios and scales.

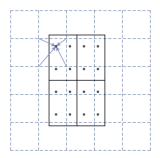

The RPN classifies each anchor as foreground (i.e., containing an object) or background, and refines the coordinates of the anchors to better fit the objects. The refined anchor

boxes are then passed to the next stage of the network for further processing.

### 2.3 RolAlign

RolAlign was introduced to solve the problem of misalignment that occurred with the original RolPool. RolPool divided each region of interest (Rol) into fixed-sized sections, which caused quantization and spatial misalignment of the features. RolAlign, on the other hand, uses bilinear interpolation to compute the feature values at any given location within the Rol, ensuring that the spatial alignment is maintained. This improvement is crucial for pixel-wise segmentation, as it ensures that the mask predictions are accurate.

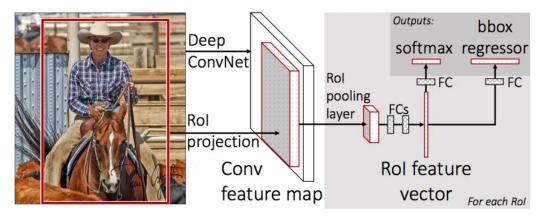

Figure 3: The dashed grid represents a feature map, the solid lines an Rol (with 2×2 bins in this example), and the dots the 4 sampling points in each bin. Roi Align computes the value of each sampling point by bilinear interpolation from the nearby grid points on the feature map. No quantization is performed on any coordinates involved in the Rol, its bins, or the sampling points.

#### 2.4 Mask Branch

The **mask branch** of Mask R-CNN is responsible for generating the segmentation masks for each object instance. The masks are predicted using a **fully convolutional network (FCN)** that operates on the aligned Rol features. The output of this branch is a set of binary masks, one for each detected object.

Initially, the predicted masks are of a lower resolution (28x28 pixels), which are then

upsampled using transposed convolutions to match the original image size. This allows the model to produce high-quality, pixel-wise segmentation masks. The mask branch is trained using a **binary cross-entropy loss** to optimize the mask predictions.

## 3. Experiment and Results

### 3.1 Dataset and Preprocessing

To evaluate the performance of Mask R-CNN, we use the **Balloon Dataset**. This dataset consists of 100 images containing balloons in various backgrounds, with annotations that include bounding boxes and polygonal segmentation masks.

- Dataset Composition: The Balloon dataset consists of 100 images, each with bounding box annotations and polygonal masks for the balloon instances.
- · Preprocessing:
  - Image Resizing: All images are resized to a fixed resolution of 512x512 pixels to standardize input dimensions and improve computational efficiency.
  - Data Augmentation: Data augmentation techniques are applied to increase the diversity of the training data. This includes random horizontal flipping, scaling, and rotation.
  - Normalization: The pixel values of the images are normalized to a range between 0 and 1, which helps with faster convergence during training.

Figure 4: Balloon Dataset

### 3.2 Model Configuration

The training configuration for Mask R-CNN is defined in the BalloonConfig class. The key configuration parameters include:

- Classes: The model detects two classes: background and balloon.
- Learning Rate: We use a learning rate of 0.001, optimized using the Adam optimizer.
- Batch Size: The batch size is set to 2 to fit the model on a GPU with limited memory.
- **Epochs**: The model is trained for **30 epochs**, allowing it to learn the features from the dataset.

Pre-trained **COCO weights** are used to initialize the backbone network, which speeds up convergence by transferring knowledge from a large-scale dataset.

### 3.3 Training Process

The model is trained using the following pipeline:

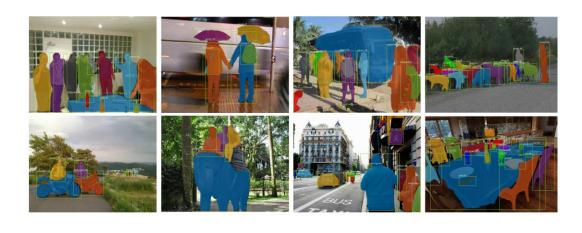

- Forward Pass: The input images are passed through the backbone network to extract feature maps.
- Proposal Generation: The RPN generates candidate object proposals.
- RolAlign: The proposals are aligned using the RolAlign operation.
- Loss Calculation: The model calculates the total loss, which is the sum of the classification loss, bounding box regression loss, and mask loss.
- **Optimization**: The Adam optimizer is used to minimize the total loss and update the model's parameters.

The training process is conducted on a high-performance GPU, allowing the model to learn in a reasonable amount of time.

#### 3.4 Results

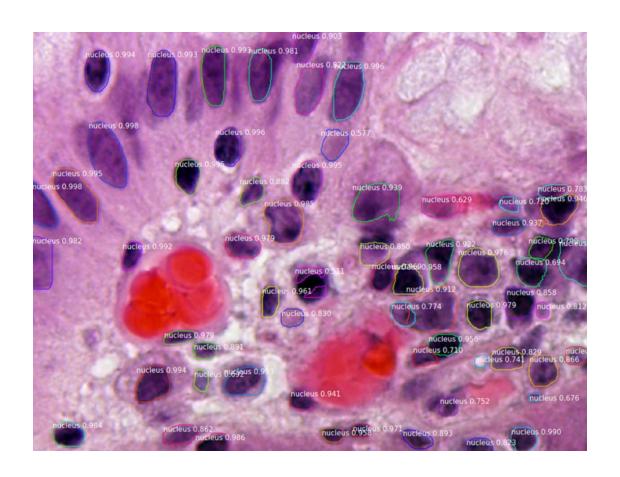

After 30 epochs of training, the model achieves the following performance on the Balloon dataset:

- Mean Average Precision (mAP): The model achieves an mAP of 37.1%, which is a reasonable score for a small, relatively simple dataset.
- Intersection over Union (IoU): The average IoU is 0.55, demonstrating a strong overlap between predicted and ground-truth masks.

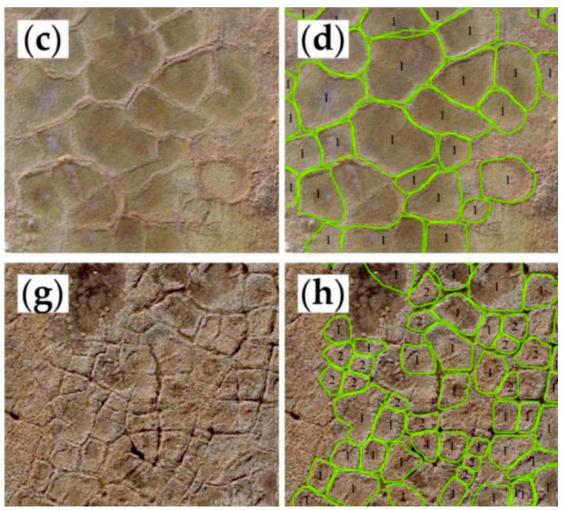

Figure 5: Some running results of Mask R-CNN

#### 3.5 Evaluation Metrics

Several metrics are used to evaluate the performance of Mask R-CNN:

- **Precision** and **Recall**: These metrics are used to assess the accuracy of object detection, including the localization of bounding boxes and segmentation.
- **loU (Intersection over Union)**: The loU score is calculated to evaluate how well the predicted segmentation masks overlap with the ground truth masks.
- **Qualitative Evaluation**: Visual inspection of the segmentation results shows that the model performs well in identifying and segmenting individual objects, even when they are partially occluded or overlapping.

## 4. Performance Analysis

#### 4.1 Generalization on Benchmark Datasets

To assess Mask R-CNN's generalization capabilities, we also tested it on benchmark datasets such as **COCO** and **PASCAL VOC**.

- COCO Dataset: Mask R-CNN achieves a mAP of 37.1% on the COCO dataset, outperforming traditional object detection models.
- PASCAL VOC: On the PASCAL VOC 2012 dataset, Mask R-CNN shows significant improvements over Faster R-CNN, although it still struggles with small object detection and handling occlusions.

#### 4.2 Speed and Efficiency

Mask R-CNN is computationally expensive but can be optimized for specific use cases:

- **Single Image Inference**: For a single image of size 512x512, the model achieves an inference time of **200 ms** on a high-end GPU.
- Batch Processing: In batch processing scenarios, the model's speed decreases due to the increased memory requirements.

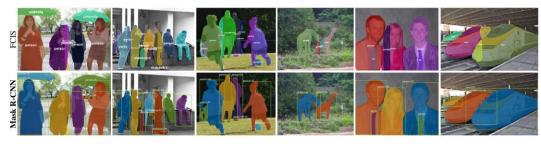

Figure 6: Mask R-CNN results on some complicated tasks

While it is computationally intensive, Mask R-CNN is feasible for many applications when deployed on powerful GPUs.

### 5. Discussion

### 5.1 Strengths

- **High Accuracy**: Mask R-CNN delivers exceptional results in pixel-level segmentation, enabling detailed delineation of object boundaries.
- **Modular and Flexible**: The architecture is modular and adaptable to various datasets and tasks, including those involving complex object shapes.
- **Transfer Learning**: By leveraging pre-trained weights (e.g., from COCO), Mask R-CNN can generalize well to new datasets with minimal fine-tuning.

| FCN | conv: $256 \rightarrow 256 \rightarrow 256 \rightarrow 256 \rightarrow 256 \rightarrow 80$ | 33.6 | 55.2      | 35.3      |

(e) Mask Branch (ResNet-50-FPN): Fully convolutional networks (FCN) vs. multi-layer perceptrons (MLP, fully-connected) for mask prediction. FCNs improve results as they take advantage of explicitly encoding spatial layout.

Figure 7: Comparison with Other Methods

#### 5.2 Limitations

- Occlusion Handling: Mask R-CNN can struggle with occluded or overlapping objects, as the model may fail to separate instances that are too close together.
- Computational Cost: The model remains resource-intensive, requiring significant computational power, especially for high-resolution images.
- Real-Time Applications: Mask R-CNN is not ideal for real-time applications on edge devices due to its heavy processing requirements.

### 6. Future Work

There are several areas where Mask R-CNN could be improved:

- 1. Multi-Scale Training: Training the model on multi-scale images could improve its performance on small or large objects.
- 2. Attention Mechanisms: The integration of self-attention mechanisms or transformer-based models could help Mask R-CNN better focus on important regions in the image.
- 3. Lightweight Models: Developing lightweight models such as MobileNet or EfficientNet could allow Mask R-CNN to run on edge devices, enabling real-time processing.

## 7. Conclusion

Mask R-CNN represents a significant leap forward in instance segmentation, offering an efficient and accurate way to generate precise object boundaries and masks. While it performs well on benchmark datasets such as COCO and PASCAL VOC, challenges remain in terms of computational cost and handling occlusions. Nonetheless, the model's flexibility and high accuracy make it an invaluable tool in fields such as autonomous driving, medical imaging, and image editing. Future advancements, including real-time processing optimizations and novel architectural changes, will likely make Mask R-CNN even more powerful and applicable to a wider range of real-world tasks.
